PSTAT 100 Homework 4

```
import numpy as np
import pandas as pd
import altair as alt
import sklearn.linear_model as lm
from sklearn.preprocessing import add_dummy_feature
```

Background: California Department of Developmental Services

From Taylor, S. A., & Mickel, A. E. (2014). Simpson's Paradox: A Data Set and Discrimination Case Study Exercise. Journal of Statistics Education, 22(1):

Most states in the USA provide services and support to individuals with developmental disabilities (e.g., intellectual disability, cerebral palsy, autism, etc.) and their families. The agency through which the State of California serves the developmentally-disabled population is the California Department of Developmental Services (DDS) ... One of the responsibilities of DDS is to allocate funds that support over 250,000 developmentally-disabled residents. A number of years ago, an allegation of discrimination was made and supported by a univariate analysis that examined average annual expenditures on consumers by ethnicity. The analysis revealed that the average annual expenditures on Hispanic consumers was approximately one-third of the average expenditures on White non-Hispanic consumers. This finding was the catalyst for further investigation; subsequently, state legislators and department managers sought consulting services from a statistician.

In this assignment, you'll analyze the deidentified DDS data published with this article to answer the question: is there evidence of ethnic or gender discrimination in allocation of DDS funds?

Aside: The JSE article focuses on what's known as Simpson's paradox, an arithmetic phenomenon in which aggregate trends across multiple groups show the *opposite* of within-group trends. We won't emphasize this topic, though the data does provide a nice illustration -- if you're interested in learning more, you can follow the embedded link to the Wikipedia entry on the subject.

Assignment objectives

You'll answer the question of interest employing exploratory and regression analysis techniques from class. In particular, you'll practice the following skills.

Exploratory analysis:

- grouped summaries for categorical variables;
- visualization techniques for categorical variables;
- hypothesis generation based on EDA.

Regression analysis:

- categorical variable encodings;
- model fitting and fit reporting;
- parameter interpretation;
- model-based visualizations.

In addition, in **communicating results** at the end of the assignment, you'll practice a few soft skills that may be helpful in thinking about how to report results for your independent class project:

- composing a concise summary (similar to an abstract) of background and key findings; and
- determining which results (figures/tables) to reproduce in a presentation context.

O. Getting acquainted with the DDS data

The data for this assignment are already tidy, so in this section you'll just familiarize yourself with basic characteristics. The first few rows of the data are shown below:

```
In [83]: dds = pd.read_csv('data/california-dds.csv')
    dds.head()
```

Out[83]:		Id	Age Cohort	Age	Gender	Expenditures	Ethnicity
	0	10210	13 to 17	17	Female	2113	White not Hispanic
	1	10409	22 to 50	37	Male	41924	White not Hispanic
	2	10486	0 to 5	3	Male	1454	Hispanic
	3	10538	18 to 21	19	Female	6400	Hispanic
	4	10568	13 to 17	13	Male	4412	White not Hispanic

Take a moment to open and read the data documentation (data > california-dds-documentation.md).

Question 0 (a). Sample characteristics

Answer the following questions based on the data documentation.

(i) Identify the observational units.

Answer: The observational units in this dataset are developmentally-disabled residents (consumers) characterized by their unique ID.

(ii) Identify the population of interest.

Answer: The population of interest are the developmentally-disabled residents in California.

(iii) What type of sample is this (e.g., census, convenience, etc.)?

Answer: This type of sample is an administrative random sample because the sample covers the entire sampling frame which is all ethnicities recorded ,but the frame does not cover the entire poluation for all ethnicites.

(iv) Is it possible to make inferences about the population based on this data?

Answer: Yes, it is possible to make inferences about population based on this data because the sample is drawn at random.

Name	Variable description	Туре	Units of measurement
ID	Unique consumer identifier	Numeric	None
Age Cohort	Binned age variable represented as six age cohorts (0-5, 6-12, 13-17, 18-21, 22-50, and 51+)	Catagorical	None
Age	Unbinned age	Numeric	Year
Gender	Male or Female	Catagorical	None
Expenditures	Dollar amount of annual expenditures spent on each consumer	Numeric	Dollar
Ethnicity	consumer ethnic groups (American Indian, Asian, Black, Hispanic, Multi-race, Native Hawaiian, Other, and White non-Hispanic)	Catagoridca	None

1. Exploratory analysis

Question 1 (a). Alleged discrimination

These data were used in a court case alleging discrimination in funding allocation by ethnicity. The basis for this claim was a calculation of the median expenditure for each group. Here you'll replicate this finding.

(i) Median expenditures by ethnicity

Construct a table of median expenditures by ethnicity.

- 1. Slice the ethnicity and expenditure variables from dds, group by ethnicity, and calculate the median expenditure. Store the result as median_expend_by_eth.
- 2. Compute the sample sizes for each ethnicity using _value_counts() : obtain a Series object indexed by ethnicity with a single column named n . You'll need to use _rename(...) to avoid having the column named Ethnicity . Store this result as ethnicity_n .
- 3. Use pd.concat(...) to append the sample sizes in ethnicity_n to the median expenditures in median expend by eth. Store the result as tbl 1.

Print tbl_1.

Out[109]:

	Expenditures	n
American Indian	41817.5	4
Asian	9369.0	129
Black	8687.0	59
Hispanic	3952.0	376
Multi Race	2622.0	26
Native Hawaiian	40727.0	3
Other	3316.5	2
White not Hispanic	15718.0	401

(ii) Do there appear to be significant differences in funding allocation by ethnicity?

If so, give an example of two groups receiving significantly different median payments.

Answer

Yes, there does appear to be significant differences in funding allocation by ethnicity. For example, multi race groups have a median funding allocation of 2,622 dollars while Native Hawaiian has a much larger median funding allocation of 40,727 dollars.

(iii) Which groups have small sample sizes? How could this affect the median expenditure in those groups?

Answer

Native Hawaiian, American Indian, and Other have small sample sizes making these median expeditures very misleading as there seems to be an insufficent amount of data. With such large expenditure amount for such little sample size, we will need more observations as these values demonstrate inaccurate data for these ethnic groups being such an outlier.

(iv) Display tbl_1 visually.

Construct a point-and-line plot of median expenditure (y) against ethnicity (x), with:

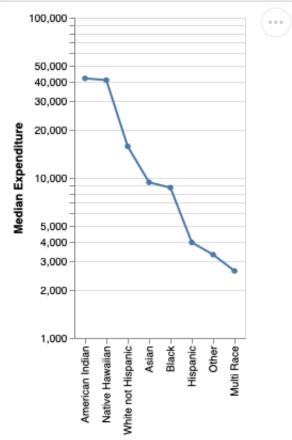

- ethnicities sorted by descending median expenditure;
- the median expenditure axis shown on the log scale;
- the y-axis labeled 'Median expenditure'; and
- no x-axis label (since the ethnicity group names are used to label the axis ticks, the label 'Ethnicity' is redundant).

Store the result as fig_1 and display the plot.

Hints:

- you'll need to use tbl_1.reset_index() to obtain the ethnicity group as a variable;
- recall that _mark_line(point = True) will add points to a line plot;
- sorting can be done using alt.X(..., sort =
 alt.EncodingSortField(field = ..., order = ...))

Question 1 (b). Age and expenditure

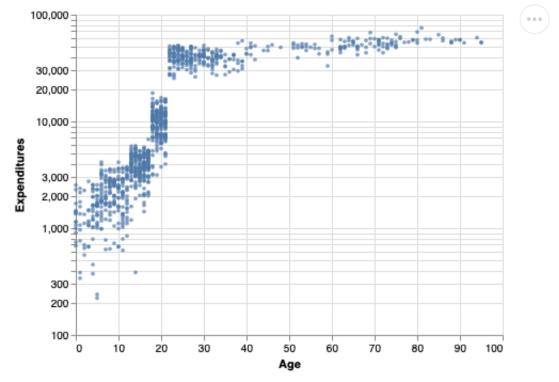

Here you'll explore how expenditure differs by age.

(i) Construct a scatterplot of expenditure (y) versus age (x).

Use the quantitative age variable (not age cohort). Display expenditure on the y axis on the log scale, and age on the x axis on the usual (linear) scale.

Store the plot as fig_2 and display the graphic.

Out[86]:

(ii) Does the relationship seem linear?

If so, describe the direction (positive/negative) and approximate strength (steep/slight) of relationship. If not, describe the pattern of relationship, if any, in 1-2 sentences.

Answer

The relationship does not seem linear because of a discountinuity in the graph, however there does seem to be a positive relationship between Age and Expenditure. Before age 30, as age rises, expediture also had a steep and steady positive incline. After age 30, Expenditure is quite stangnat and seems to have just a slight increase as age increases towards 100.

(iii) Overall, how does expenditure tend to change as age increases?

Answer

Overall, as age increases, expenditure tends to increase as well.

(iv) What might explain the sudden increase in expenditure after age 20?

Answer

The sudden increase in expenditure after age 20 may be a result of a need for caregivers to take longer care of the developmentally-disabled resident. It is possible that as they get older, their condition worsens so they would need caregivers for a longer period of time. Also, at the age of 20, many of the consumers would leave their parents' home so more funding is needed for caregivers.

Precisely because recipients have different needs at different ages that translate to jumps in expenditure, age has been discretized into age cohorts defined based on need level. Going forward, we'll work with these age cohorts -- by treating age as discrete, we won't need to attempt to model the discontinuities in the relationship between age and expenditure.

The cohort labels are stored as Age Cohort in the dataset. There are six cohorts; the cell below coerces the labels to an ordered category and prints the category levels.

Here is an explanation of how the cohort age boundaries were chosen:

The 0-5 cohort (preschool age) has the fewest needs and requires the least amount of funding. For the 6-12 cohort (elementary school age) and 13-17 (high school age), a number of needed services are provided by schools. The 18-21 cohort is typically in a transition phase as the consumers begin moving out from their parents' homes into community centers or living on their own. The majority of those in the 22-50 cohort no longer live with their parents but may still receive some support from their family. Those in the 51+ cohort have the most needs and require the most amount of funding because they are living on their own or in community centers and often have no living parents.

Question 1 (c). Age and ethnicity

Here you'll explore the age structure of each ethnic group in the sample.

(i) Group the data by ethnic group and tabulate the sample sizes for each group.

Use dds_cat so that the order of age cohorts is preserved. Write a chain that does the following.

- 1. Group by age cohort and ethnicity.
- 2. Slice the Id variable, which is unique to recipient in the sample.
- 3. Count the number of recipients in each group using .count().
- 4. Reset the index so that age cohort and ethnicity are dataframe columns.
- 5. Rename the column of ID counts 'n'.

Store the result as samp_sizes and print the first four rows.

```
In [111... # solution
    samp_sizes = dds_cat.groupby(['Age Cohort', 'Ethnicity']).Id.count(
    ).reset_index().rename(columns={'Id':'n'})

# print
    samp_sizes
```

Out[111]:

	Age Cohort	Ethnicity	n
0	0 to 5	American Indian	0
1	0 to 5	Asian	8
2	0 to 5	Black	3
3	0 to 5	Hispanic	44
4	0 to 5	Multi Race	7
5	0 to 5	Native Hawaiian	0
6	0 to 5	Other	0
7	0 to 5	White not Hispanic	20
8	6 to 12	American Indian	0
9	6 to 12	Asian	18
10	6 to 12	Black	11
11	6 to 12	Hispanic	91
12	6 to 12	Multi Race	9
13	6 to 12	Native Hawaiian	0
14	6 to 12	Other	0

15	6 to 12	White not Hispanic	46
16	13 to 17	American Indian	1
17	13 to 17	Asian	20
18	13 to 17	Black	12
19	13 to 17	Hispanic	103
20	13 to 17	Multi Race	7
21	13 to 17	Native Hawaiian	0
22	13 to 17	Other	2
23	13 to 17	White not Hispanic	67
24	18 to 21	American Indian	0
25	18 to 21	Asian	41
26	18 to 21	Black	9
27	18 to 21	Hispanic	78
28	18 to 21	Multi Race	2
29	18 to 21	Native Hawaiian	0
30	18 to 21	Other	0
31	18 to 21	White not Hispanic	69
32	22 to 50	American Indian	1
33	22 to 50	Asian	29
34	22 to 50	Black	17
35	22 to 50	Hispanic	43
36	22 to 50	Multi Race	1
37	22 to 50	Native Hawaiian	2
38	22 to 50	Other	0
39	22 to 50	White not Hispanic	133
40	51+	American Indian	2
41	51+	Asian	13
42	51+	Black	7
43	51+	Hispanic	17
44	51+	Multi Race	0
45	51+	Native Hawaiian	1
46	51+	Other	0
47	51+	White not Hispanic	66

(ii) Visualize the age structure of each ethnic group in the sample.

Construct a point-and-line plot of the sample size against age cohort by ethnicity.

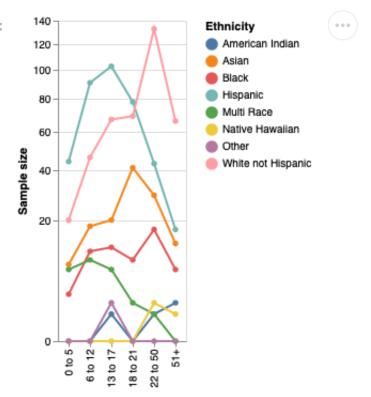

- 1. To preserve the ordering of age cohorts, create a new column in samp_sizes called cohort_order that contains an integer encoding of the cohort labels in order. To obtain the integer encoding, slice the age cohort variable as a series and use series.cat.codes.
- 2. Construct an Altair chart based on samp_sizes with:
 - sample size (n) on the y axis;
 - the y axis titled 'Sample size' and displayed on a square root scale;
 - age cohort on the x axis, ordered by the cohort variable you created;
 - the x axis unlabeled; and
 - ethnic group mapped to color.

Store the plot as fig_3 and display the graphic.

```
(Hint: sorting can be done using alt.X(..., sort = alt.EncodingSortField(field = ..., order = ...)).)
```

```
In [112... # add column with category codes
samp_sizes['cohort_order'] = samp_sizes['Age Cohort'].cat.codes
# construct plot
fig_3 = alt.Chart(samp_sizes).mark_line(point=True).encode(
    x = alt.X('Age Cohort',title = '', sort = alt.EncodingSortField(
        field = 'cohort_order', order = 'ascending')),
    y = alt.Y('n' ,title = 'Sample size',
        scale = alt.Scale(type = 'sqrt')),
    color = 'Ethnicity'
)
# display
fig_3
```

Out[112]:

(iii) Are there differences in age structure?

If so, identify one specific example of two ethnic groups with different age structures and describe how the age structures differ.

Answer

Two ethnic groups with different age structures are White not Hispanic and Native Americans. We can see that there are 140 people from ages 22 to 50 in the White ethnic group whereas the Native Americans only have about 5 in this age group. Native Americans have some of the lowest amounts of people in eah age group making it very different from other ethnic groups.

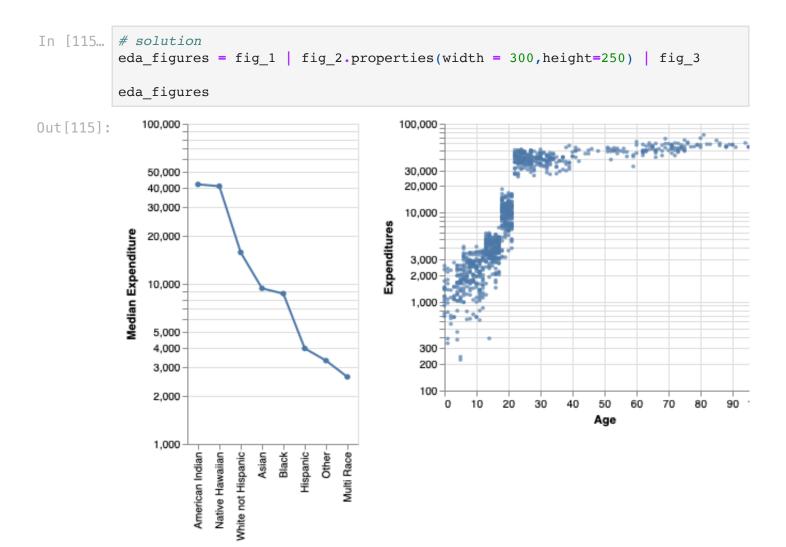

Question 1 (d). Correcting for age

Here you'll consider how the age structure among ethnic groups might be related to the observed differences in median expenditure.

(i) Combine your figures 1, 2, and 3.

Place your figures together in three panels on a single row. You'll need to adjust the width of figure 2 (expenditure vs. age) so that the panels don't get cut off in rendering your notebook.

Store the figure panel as eda_figures and display the graphic.

(ii) Why is the median expenditure for the multiracial group so low?

Look at the age distribution for Multi Race and consider the age-expenditure relationship. Can you explain why the median expenditure for this group might be lower than the others? Answer in 1-2 sentences.

Answer

The sample size for Multi-race decreases as age increases with most being between 6 and 17. This gives us an average expenditure amount of between 2,000 and 5,000. Therefore, as we have seen that median expenditure seems to increase as age increases, a lack of older consumers gives multi-race a rather low expenditure value.

(iii) Why is the median expenditure for the American Indian group so high?

Print the rows of dds_cat for this group (there aren't very many) and answer the question based on inspecting the rows.

```
In [91]: # solution
   dds_cat[dds_cat.Ethnicity == 'American Indian']
```

Out[91]:

	ld	Age Cohort	Age	Gender	Expenditures	Ethnicity
231	30234	51+	78	Female	55430	American Indian
575	61498	13 to 17	13	Female	3726	American Indian
730	74721	51+	90	Female	58392	American Indian
788	79645	22 to 50	32	Male	28205	American Indian

Answer

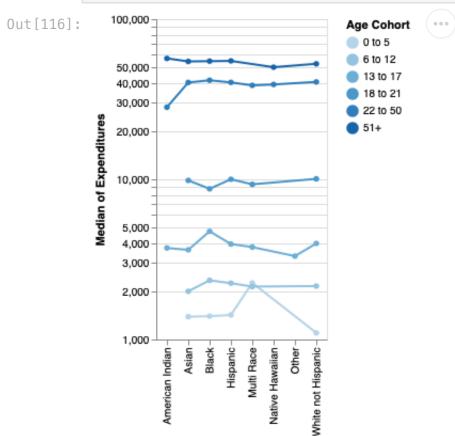

The median expenditure for the American Indian group is so high because a majority of the people in the group are in the 51+ age cohort and have the most needs to require the most amount of funding possible since they are elderly and living on thier own.

(iv) Plot expenditure against ethnicity by age.

Hopefully, the last few prompts convinced you that the apparent discrimination *could* simply be an artefact of differing age structure. You can investigate this by plotting median expenditure against ethnicity, as in figure 1, but now also correcting for age cohort.

- To preserve the ordering of age cohorts, create a new column in dds_cat called cohort_order that contains an integer encoding of the cohort labels in order. To obtain the integer encoding, slice the age cohort variable as a series and use series.cat.codes.
- 2. Construct an Altair point-and-line chart based on dds_cat with:
 - ethnicity on the x axis;
 - no x axis label;
 - median expenditure on the y axis (hint: altair can parse
 median(variablename) within an axis specification);
 - the y axis displayed on the log scale;
 - age cohort mapped to color as an ordinal variable (meaning, use :0 in the variable specification) and sorted in order of the cohort_order variable you created; and
 - lines connecting points that display the median expenditure for each ethnicity and cohort, with one line per age cohort.

Store the result as fig_4 and display the graphic.

(v) Do the data reflect a difference in median expenditure by ethnicity after accounting for age?

Answer based on figure 4 in 1-2 sentences.

Answer

Overall, we do not think the data reflect a difference in median expenditure by ethnicity after accounting for age. We can see that younger people tend to have less median expediture overall across all ethnicities as well as older people have high median expeditures across all ethnicites. Therefore, ethnicity may not be a large factor.

2. Regression analysis

Now that you've thoroughly explored the data, you'll use a linear model in this part to estimate the differences in median expenditure that you observed graphically in part 1.

More specifically, you'll model the log of expenditures (response variable) as a function of gender, age cohort, and ethnicity:

$$\log(\mathrm{expend}_i) = \beta_0 + \beta_1(6-12)_i + \dots + \beta_5(51+)_i + \beta_6 \mathrm{male}_i + \beta_7 \mathrm{hispanic}_i + \dots + \beta_6 \mathrm{male}_i$$

In this model, *all* of the explanatory variables are categorical and encoded using indicators; in this case, the linear model coefficients capture means for each group.

Because this model is a little different than the examples you've seen so far in two respects -- the response variable is log-transformed and all explanatory variables are categorical -- some comments are provided below on these features. You can review or skip the comments, depending on your level of interest in understanding the model better mathematically.

Commments about parameter interpretation

In particular, each coefficient represents a difference in means from the 'baseline' group. All indicators are zero for a white male recipient between ages 0 and 5, so this is the baseline group and:

$$\mathbb{E}(\log(\text{expend}) \mid \text{male}, \text{white}, 0\text{-}5) = \beta_1$$

Then, the expected log expenditure for a hispanic male recipient between ages 0 and 5 is:

$$\mathbb{E}\left(\log(\text{expend})\mid \text{male, hispanic, 0-5}\right)=\beta_0+\beta_7$$

So β_7 is the difference in mean log expenditure between hispanic and white recipients after accounting for gender and age. The other parameters have similar interpretations.

While the calculation shown above may seem a little foreign, you should know that the parameters represent marginal differences in means between genders (holding age and ethnicity fixed), between ages (holding gender and ethnicity fixed), and between ethnicities (holding age and gender fixed).

Comments about the log transformation

The response in this model is the *log* of expenditures (this gives a better model for a variety of reasons). The statistical assumption then becomes that:

$$\log(\mathrm{expend})_i \sim N\left(\mathbf{x}_i'eta,\sigma^2
ight)$$

If the log of a random variable Y is normal, then Y is known as a *lognormal* random variable; it can be shown mathematically that the exponentiated mean of $\log Y$ is the median of Y. As a consequence, according to our model:

$$median(expend_i) = exp\{\mathbf{x}_i'\beta\}$$

You'll work on the log scale throughout to avoid complicating matters, but know that this model for the log of expenditures is *equivalently* a model of the median expenditures.

Reordering categories

The cell below reorders the category levels to match the model written above. To ensure the parameters appear in the proper order, this reordering is done for you.

```
In [93]: # remove ID and quantitative age
    reg_data = dds_cat.copy().drop(columns = ['Id', 'Age'])

# reorder ethnicity
    reg_data['Ethnicity'] = reg_data.Ethnicity.cat.as_ordered().cat.reorder_cate
        reg_data.Ethnicity.cat.categories[[7, 3, 2, 1, 5, 0, 4, 6]]
)

# reorder gender
    reg_data['Gender'] = reg_data.Gender.cat.as_ordered().cat.reorder_categories
```

Question 2 (a). Data preprocessing

Here you'll extract the quantities -- explanatory variable matrix and response vector -- needed to fit the linear model.

(i) Categorical variable encoding.

Use $pd.get_dummies(...)$ to encode the variables in reg_data as indicators. Be sure to set $drop_first = True$. Store the encoded categorical variables as x_df and print the first three rows and six columns. (There should be 13 columns in total.)

(*Hint*: reg_data can be passed directly to get_dummies(...), and quantitative variables will be unaffected; a quick way to find x_df is to pass reg_data to this function and then drop the quantitative variables.)

```
In [94]: # solution
   x_df = pd.get_dummies(reg_data, columns = ['Age Cohort', 'Gender','Ethnicity
   #print
   x_df.head(3)
```

	Age Cohort_6 to 12	Age Cohort_13 to 17	Age Cohort_18 to 21	Age Cohort_22 to 50	Age Cohort_51+	Gender_Female	Ethnicity_Hispan
0	0	1	0	0	0	1	
1	0	0	0	1	0	0	
2	0	0	0	0	0	0	

(ii) Add intercept.

Out [94]:

Add an intercept column -- a column of ones -- to x_df using add_dummy_feature(...) . Store the result (an array) as x_mx and print the first three rows and six columns.

```
In [95]: # solution
x_mx = add_dummy_feature(x_df, value = 1)
print(x_mx[0:3, 0:6])

[[1. 0. 1. 0. 0. 0.]
[1. 0. 0. 0. 1. 0.]
[1. 0. 0. 0. 0. 0.]]
```

(iii) Response variable.

Log-transform the expenditures column of reg_data and store the result in array format as y . Print the first ten entries of y .

```
In [96]: # solution
y = np.array(np.log(reg_data['Expenditures']))
print(y[0:10])

[ 7.65586402 10.64361373  7.28207366  8.76405327  8.39208338  8.42639283
    8.27257061  8.26178468  8.5213844  7.96797318]
```

Question 2 (b). Model fitting

In this part you'll fit the linear model and summarize the results. You may find it helpful to have lab 6 open as an example to follow througout.

(i) Compute the estimates.

Configure a linear regression module and store the result as mlr; fit the model to x_mx and y. Be sure **not** to fit an intercept separately, since there's already an intercept column in x_mx .

(You do not need to show any output for this part.)

```
In [97]: # solution
mlr = lm.LinearRegression(fit_intercept = False)
mlr.fit(x_mx, y)
```

Out[97]: LinearRegression(fit_intercept=False)

(ii) Parameter estimate table.

Construct a table of the estimates and standard errors for each coefficient, and the estimate for the error variance parameter. The table should have two columns, 'estimate' and 'standard error', and rows should be indexed by parameter name. Follow the steps below.

- 1. Store the dimensions of $x_m x$ as n and p.
- 2. Compute $(\mathbf{X}'\mathbf{X})$; store the result as x + x = 1.
- 3. Compute $(\mathbf{X}'\mathbf{X})^{-1}$; store the result as xtx_inv .
- 4. Compute the residuals (as an array); store the result as resid.
 - (You can compute the fitted values as a separate step, or not, depending on your preference.)
- 5. Compute the error variance estimate, $var(resids) \times \frac{n-1}{n-p}$; store the result as sigmasqhat.
- 6. Compute the variance-covariance matrix of the coefficient estimates $\hat{\mathbf{V}} = \hat{\sigma}^2(\mathbf{X}'\mathbf{X})^{-1}$; store the result as v_{hat} .
- 7. Compute the coefficient standard errors, $\sqrt{\hat{v}_{ii}}$; store the result (an array) as coef_se .
 - Append an NaN (float('nan')) to the array (for the error variance estimate).
- 8. Create an array of coefficient labels by appending 'intercept' to the column names of x_df , followed by 'error_variance'; store the result as $coef_labels$.
- 9. Create an array of estimates by appending the fitted coefficients with sigmasqhat; store the result as coef_estimates.
- 10. Create a dataframe with coef_estimates as one column, coef_se as another column, and indexed by coef_labels. Store the result as coef_table.

Print coef_table.

```
In [98]: # store dimensions
         n,p = x_mx.shape
         # compute x'x
         xtx = x_mx.transpose().dot(x_mx)
         # compute x'x inverse
         xtx_inv = np.linalg.inv(xtx)
         # compute residuals
         fitted_mlr = mlr.predict(x_mx)
         resid = y - fitted_mlr
         # compute error variance estimate
         sigmasqhat = resid.var() * ((n-1)/(n-p))
         # compute variance-covariance matrix
         v_hat = xtx_inv * sigmasqhat
         # compute standard errors
         coef_se = np.sqrt(v_hat.diagonal())
         coef_se = np.append(coef_se,float('nan'))
         # coefficient labels
         coef_labels = np.append('intercept',x_df.columns.values.tolist())
         coef_labels = np.append(coef_labels, 'error variance')
         # estimates
         coef_estimates = np.append(mlr.coef_, sigmasqhat)
         # summary table
         coef_table = pd.DataFrame(
             data = {'Coefficent Estimates':coef_estimates,'Standard Error':coef_se},
             index = coef labels
         # print
         coef_table
```

	Coefficent Estimates	Standard Error
intercept	7.092439	0.041640
Age Cohort_6 to 12	0.490276	0.043833
Age Cohort_13 to 17	1.101010	0.042761
Age Cohort_18 to 21	2.023844	0.043435
Age Cohort_22 to 50	3.470836	0.043500
Age Cohort_51+	3.762393	0.049536
Gender_Female	0.039784	0.020739
Ethnicity_Hispanic	0.038594	0.024881
Ethnicity_Black	0.041713	0.045702
Ethnicity_Asian	-0.021103	0.033454
Ethnicity_Native Hawaiian	-0.030725	0.189872
Ethnicity_American Indian	-0.054396	0.164828
Ethnicity_Multi Race	0.041024	0.067646
Ethnicity_Other	-0.189877	0.232793
error variance	0.106898	NaN

Now look at both the estimates and standard errors for each level of each categorical variable; if some estimates are large for at least one level and the standard errors aren't too big, then estimated mean log expenditures differ according to the value of that variable when the other variables are held constant.

For example: the estimate for <code>Gender_Female</code> is 0.04; that means that, if age and ethnicity are held fixed, the estimated difference in mean log expenditure between female and male recipients is 0.04. If $\log(a) - \log(b) = 0.04$, then $\frac{a}{b} = e^{0.04} \approx 1.041$; so the estimated expenditures (not on the log scale) differ by a factor of about 1. Further, the standard error is 0.02, so the estimate is within 2SE of 0; the difference could well be zero. So the model suggests there is no difference in expenditure by gender.

(iii) Do the parameter estimates suggest differences in expenditure by age or ethnicity?

First consider the estimates and standard errors for each level of age, and state whether any differences in mean log expenditure between levels appear significant; if so, cite one example. Then do the same for the levels of ethnicity. Answer in 2-4 sentences.

(Hint: it may be helpful scratch work to exponentiate the coefficient estimates and consider whether they differ by much from 1.)

In [99]: # exponentiate age (not required) np.exp(coef_table.iloc[1:6])

Out[99]:

	Coefficent Estimates	Standard Error
Age Cohort_6 to 12	1.632767	1.044808
Age Cohort_13 to 17	3.007203	1.043689
Age Cohort_18 to 21	7.567356	1.044392
Age Cohort_22 to 50	32.163632	1.044460
Age Cohort_51+	43.051330	1.050783

In [100... # exponentiate ethnicity (not requried) np.exp(coef_table.iloc[7:14])

Out[100]:

	Coefficent Estimates	Standard Error
Ethnicity_Hispanic	1.039348	1.025193
Ethnicity_Black	1.042595	1.046762
Ethnicity_Asian	0.979118	1.034019
Ethnicity_Native Hawaiian	0.969742	1.209095
Ethnicity_American Indian	0.947057	1.179190
Ethnicity_Multi Race	1.041877	1.069987
Ethnicity_Other	0.827061	1.262121

Answer

Yes, there are differences in expenditure between different ages. One example is the Age Cohort_51+ which has an exponential coefficent estimate of 43.051330 which is much larger than an exponential coefficent estimate of 1.632767. The error bound does not include 0 which suggests that if all other variables are held fixed, the estimated increase in expenditure is 43.051330 for those in age cohort of 51+.

There are no differences in expenditure by ethnicities. For example, the estimate for Hispanic is 1.039348 with a standard error of 1.025193 and after subtracting estimates by standard error our value is 0.014155 (close to 0). The Coefficent Estimates and Standard Error for all ethnicities are relatively similar to each other which indicates that there are no difference between ethnicity groups.

Now as a final step in the analysis, you'll visualize your results. The idea is simple: plot the estimated mean log expenditures for each group. Essentially you'll make a version of your figure 4 from part 1 in which the points are estimated rather than observed. So the model visualization graphic will look similar to this:

In order to construct a 'model version' of this plot, however, you'll need to generate estimated mean log expenditures for each unique combination of categorical variable levels. The cell below generates a 'grid' of every such combination.

```
In [102... # store unique levels of each categorical variable
         genders = reg_data.Gender.unique()
         ethnicities = reg_data.Ethnicity.unique()
         ages = reg_data['Age Cohort'].unique()
         # generate grid of each unique combination of variable levels
         gx, ex, ax = np.meshgrid(genders, ethnicities, ages)
         ngrid = len(genders)*len(ethnicities)*len(ages)
         grid mx = np.vstack([ax.reshape(ngrid), gx.reshape(ngrid), ex.reshape(ngrid)
         grid_df = pd.DataFrame(grid_mx, columns = ['age', 'gender', 'ethnicity']).as
             {'gender': 'category', 'ethnicity': 'category', 'age': 'category'}
         # reorder category levels so consistent with input data
         grid_df['ethnicity'] = grid_df.ethnicity.cat.as_ordered().cat.reorder_catego
             grid_df.ethnicity.cat.categories[[7, 3, 2, 1, 5, 0, 4, 6]]
         grid_df['gender'] = grid_df.gender.cat.as_ordered().cat.reorder_categories([
         grid df['age'] = grid df.age.cat.as ordered().cat.reorder categories(
             grid_df.age.cat.categories[[0, 5, 1, 2, 3, 4]]
         grid df['cohort order'] = grid df.age.cat.codes
         # preview
         grid df.head()
```

Out[102]:		age	gender	ethnicity	cohort_order
	0	13 to 17	Female	White not Hispanic	2
	1	22 to 50	Female	White not Hispanic	4
	2	0 to 5	Female	White not Hispanic	0
	3	18 to 21	Female	White not Hispanic	3
	4	51+	Female	White not Hispanic	5

Question 2 (c). Model visualization

Your task in this question will be to add fitted values and standard errors to the grid above and then plot it.

(i) Create an explanatory variable matrix from the grid.

Pretend for a moment that you're going to treat <code>grid_df</code> as if it were the data. Create a new <code>x_mx</code> based on <code>grid_df</code>:

- 1. Use pd.get_dummies(...) to obtain the indicator variable encoding of grid_df; store the result as pred_df.
- 2. Add an intercept column to pred_df using add_dummy_feature(...); store the result (an array) as pred_mx.

Print the first three rows and six columns of pred_mx.

(ii) Compute fitted values and standard errors on the grid.

Now add a new column to <code>grid_df</code> called <code>expenditure</code> that contains the estimated log expenditure (*hint*: use <code>mlr_predict(...)</code> with your result from (i) immediately above).

```
In [104... # solution
    grid_df['expenditure'] = mlr.predict(pred_mx)
```

The cell below adds the standard errors for estimated log expenditure.

```
In [105... # add standard errors
grid_df['expenditure_se'] = np.sqrt(pred_mx.dot(xtx_inv).dot(pred_mx.transpc
```

(iii) Plot the estimated means and standard errors.

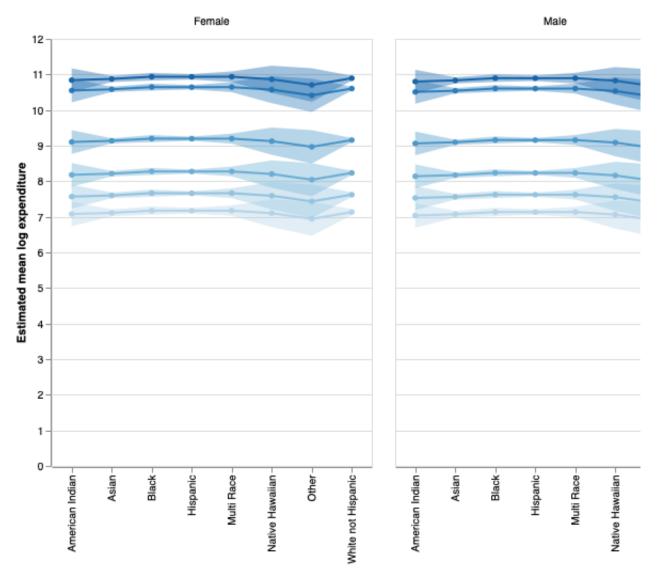

Construct a model visualization matching figure 4 in the following steps.

- 1. Construct a point-and-line plot called lines based on grid_df with:
 - ethnicity on the x axis;
 - no x axis title;
 - log expenditure on the y axis;
 - the y axis title 'Estimated mean log expenditure';
 - age cohort mapped to the color encoding channel as an *ordinal* variable and shown in ascending cohort order (refer back to your codes for figure 4).
- 2. Construct an error band plot called bands based on grid_df with:
 - a .transform_calculate(...) step computing lower and upper band boundaries
 - $lwr = expenditure 2 \times expenditure_se$ and
 - upr = expenditure + $2 \times$ expenditure_se;
 - ethnicity on the x axis;
 - no x axis title;
 - lwr and upr passed to the y and y2 encoding channels;
 - the y channel titled 'Estimated mean log expenditure';
 - age cohort mapped to the color channel exactly as in lines.
- 3. Layer lines and bands and facet the layered chart into columns according to gender. Store the result as fig_5.

Display fig_5.

```
In [117... # point and line plot
         lines = alt.Chart(grid df).mark line(point = True).encode(
             x = alt.X('ethnicity',title = ''),
             y = alt.Y('expenditure' ,title = 'Estimated mean log expenditure'),
             color = alt.Color('age:0', sort = alt.EncodingSortField(
                 field = 'cohort_order', order = 'ascending'))
         # error bands
         bands = alt.Chart(grid_df).transform_calculate(
             lwr = 'datum.expenditure - (2 * datum.expenditure se)',
             upr = 'datum.expenditure + (2 * datum.expenditure_se)'
         ).mark_errorband(opacity = 0.4).encode(
                 x = alt.X('ethnicity', title=''),
                 y = alt.Y('lwr:Q',title= 'Estimated mean log expenditure'),
                 y2 = 'upr:Q',
                 color = alt.Color('age:0', sort = alt.EncodingSortField(
                     field = 'cohort order', order = 'ascending'))
         # layer and facet
         fig_5 = (lines + bands).properties(
             width = 300, height = 400).facet(column = 'gender')
         # display
         fig_5
```

Out[117]: gender

(iv) Sanity check.

Does the model visualization seem to accurately reflect the pattern in your exploratory plots? Answer in 1 sentence.

Answer

I do think the model visualization seem to accurately reflect the pattern in the exploratory plots because of the fact that there are significant differences in the estimated mean log expenditure between the age levels but not much variation amoungst ethnic groups.

(v) Which estimates have greater uncertainty and why?

Identify the ethnic groups for which the uncertainty band is relatively wide in the plot. Why might uncertainty be higher for these groups? Answer in 2 sentences.

(*Hint*: it may help to refer to figure 3.)

Answer

The ethnic groups with a relatively wide uncertainty bands in the plot are the American Indian, Native Hawaiian, and Other group. Uncertainty seems to be higher for these groups due to thier sample sizes being significantly small than the rest of the data for other ethnic groups.

3. Communicating results

Review your exploratory and regression analyses above, and then answer the following questions.

Question 3 (a). Summary

Write a one-paragraph summary of your analysis. Focus on answering the question, 'do the data provide evidence of ethnic or gender discrimination in allocation of DDS funds?'

Your summary should include the following:

- a one-sentence description of the data indicating observations, variables, and whether they are a random sample;
- one to two sentences describing any important exploratory findings;
- a one-sentence description of the method you used to analyze the data (don't worry about capturing every detail);
- one sentence desribing findings of the analysis;
- an answer to the question.

Answer

A random sample was conducted to gather data about DDS expenditure information for several different ethnic groups along with infomation on these consumers such as ID, age, and gender. After making some exploratory plots, we found a difference in the amount of DDS expenditure when relating to the age of the consumer. Using multiple linear regression, we were able to neatly visualize the relationships between the expenditures, ages, gender and ethnicities of consumers. We found that the ethnic group and gender of the consumer does not play a factor in the amount of allocated DDS expenditures; however, age does play a factor as consumers in higher age groups have higher funding compared to the younger age groups. We can say that there is a positive relationship between age and median expenditures of disable residents seeking aid in California. Hence, the data does not provide evidence of ethnic or gender discrimination in allocation of DDS funds.

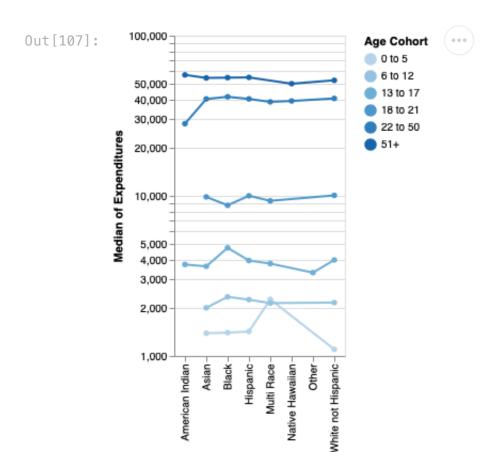

Question 3 (b). Supporting information

Choose one table or figure from part 1 and one table and figure from part 2 that support your summary of results. Write a caption for each of your choices.

(i) First figure/table.

Figure 4 shows the median expenditure of each ethnicty separated by age cohort. The points determine the value of each expenditure and are connected to form a line. This helps to show that, across all ethnicities, the median expenditure is similar for each different age cohort.

In [107... # show figure/table fig 4

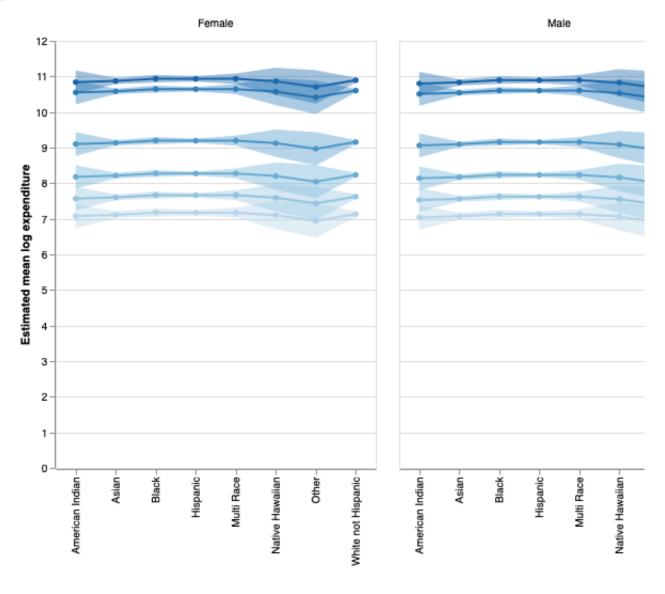

(ii) Second figure/table.

Figure 5 shows the mean log expenditures for each ethnicity, separated by age cohort, and split by sex into 2 separate plots. The points determine the value of each mean log expenditure and are connected to form a line. This helps to show that, across all ethnicities, the mean log expenditure is similar for each different age cohort. Furthermore, the lines also seem identical for both sexes and shows no differene in the mean log expenditure based on gender.

In [108...

show figure/table
fig_5

Out[108]: gender

Submission Checklist

- 1. Save file to confirm all changes are on disk
- 2. Run Kernel > Restart & Run All to execute all code from top to bottom
- 3. Save file again to write any new output to disk
- 4. Select File > Download as > HTML.
- 5. Open in Google Chrome and print to PDF on A3 paper in portrait orientation.
- 6. Submit to Gradescope
